

1 Q. In the response to CA-70-NLH, there is an indication that Hydro uses
2 Microsoft Excel in preparing operating load forecasts. Please respond to the
3 following:
4

5 (a) Is an operating load forecast simply a load forecast? If not, please
6 explain the difference between a load forecast and an operating load
7 forecast?

8 (b) How frequently is the load forecast updated?

9 (c) How long is the forecast period for a load forecast?

10 (d) If the answer to (c) is less than ten years, please explain why this
11 duration is adequate for capacity planning purposes?

12 (e) Provide a copy of the Microsoft Excel spreadsheets that have been
13 used to develop the last three load forecasts. Clearly identify all
14 variables, parameters, and inputs. Identify the source of all inputs.
15 Please ensure that the spreadsheets are not password protected and
16 that none of the cells are locked.
17
18

19 A. (a) Hydro's Operating Load Forecast (OPLF) is a monthly five-year
20 forecast of Hydro's direct sales or bulk deliveries and net requirements
21 including system transmission losses. The OPLF is used for
22 operational planning, generation scheduling, budgeting, and Cost of
23 Service purposes. The OPLF projections for 2006 and 2007 are
24 summarized in J.R. Haynes Schedules III, IV and V.
25

26 Hydro's long-term load forecast is an annual twenty-year planning
27 load forecast used for generation expansion planning and analysis.
28 Long-term load forecasts are prepared for all power systems in the

Province falling under Hydro's purview. The focus of this analytical effort is the twenty-year planning load forecast (PLF) for the Island Interconnected system. The first ten years of Hydro's current load forecast is presented in Regulated Activities: Evidence Table 4.

As CA 70 NLH already provided information on Hydro's operating load forecast, the information that follows pertains to Hydro's long-term forecast.

The long-term load forecast is prepared using an econometric and identity model housed and maintained within EViews, a program for statistical/econometric analysis and forecasting. The important inputs to the long-term model include energy prices and provincial macroeconomic indicators including housing starts, GDP, personal disposable income, the outlook for existing Industrial Customers and the provision, as appropriate, for new industrial or resource developments.

(b) The long-term load forecast is prepared annually, beginning in the fall and normally completed in early winter.

(c) The long-term load forecast is prepared for a period of no less than twenty years.

(d) Please see (c).

(e) As indicated in (a), Hydro's PLF is carried out in EViews, a commercial software platform that Hydro is not able to provide in a Request for Information.

1
2 EViews exports its output to Excel files and the PLF summaries for
3 2004, 2005, and 2006 are attached in table format and Excel
4 spreadsheets. At this time, Hydro has not identified all variables,
5 parameters, and inputs for the 2004, 2005, and 2006 PLFs
6 undertaken in EViews due to the scope of the undertaking. The
7 macroeconomic inputs for the PLF analysis are procured from the
8 Provincial Government's Department of Finance (Economic and
9 Statistics). Hydro's direct industrial load assumptions in the long term
10 forecast are consistent with the current operating load forecast.
