

1 Q. What is the maximum wind capacity sustainable on the Island under both options
2 (Muskrat Falls LIL HVDC and the Isolated Island)?
3
4

5 A. The 2004 NL Hydro study “ An Assessment of Limitations For Non- Dispatchable
6 Generation On the Newfoundland Island System “ (Exhibit 61) established two
7 limits regarding the possible level of wind generation integration on the Isolated
8 Island system, an economic limit and a maximum technical limit. The study
9 determined that for wind generation in excess of 80 MW there would be a
10 significant increase in the risk of spill at the hydroelectric reservoirs particularly
11 during the spring run off diminishing the economic advantage of additional wind
12 generation. The study further determined that for wind generation above 130 MW
13 it would not always be possible to maintain system stability particularly during
14 periods of light load and during these periods wind generation would have to be
15 curtailed.
16

17 The limits identified in the 2004 study are still applicable today. However, as load
18 grows, the Isolated Island system should be able to accommodate additional wind
19 generation. It has been suggested that the system should be able to accommodate
20 an additional 100 MW of wind in the 2025 timeframe and a further 100 MW around
21 2035. Nalcor has not studied this in detail but will undertake studies prior to DG3.
22

23 Nalcor has not completed an analysis to establish the level of wind generation that
24 could be sustained in the Muskrat Falls LIL HVDC option. However, given that this
25 option will include at least one interconnection to the North American electrical
26 grid and that there will be considerable hydroelectric capacity both in Labrador and
27 on the Island to provide backup it would not be unreasonable to consider an

1 additional 400 MW of wind generation on the Island. Nalcor will be analysing this as
2 part of the analysis that will be completed prior to DG3.
