

1 Q. Reference: *Probabilistic Based Transmission Reliability Summary Report*, Appendix  
2 A, Page 28 of 56.

3 *“Based on the Nalcor study the following are the expected failure rates and repair*  
4 *times for the HVDC overhead lines.*

- 5 • *Average failure rate per pole (based on 1100km length): 2.101/year*
- 6 • *Average repair time: 1.78 hours*
- 7 • *Average common mode failure rate: 0.02/year/100km*
- 8 • *Average common mode repair time: 24 hours”*

9 Please provide the Labrador Island Link failure rates per pole, and common mode  
10 failure rates, due purely to severe weather events. Please present the response in  
11 ‘failures/year’.

12

13

14 A. The per pole failures rates due to transmission line events are based on CIGRE  
15 statistics. These statistics do not include details relating to the specific cause of  
16 failure. Therefore, there is no basis for an estimation of failures rates due to severe  
17 weather events for the numbers presented above.

18

19 The common mode failure rate of 0.02 per year per 100 km is an estimated value  
20 provided by SNC Lavalin where it was anticipated that common mode failures  
21 within the industry average data would occur one order of magnitude less than a  
22 single pole failure. Industry wide bipole failure rates would depend on the design  
23 characteristics of the systems, and, if weather related, the severity of the weather  
24 experienced. The Labrador Island Link is designed such that the overhead  
25 transmission line common mode failures should only occur as a result of a structural  
26 failure of a transmission tower and as a result should be based on the reliability

1 return periods. It is therefore anticipated that common mode failures for weather  
2 would occur at a rate of 0.002/year for sections of the Labrador Island Link on the  
3 Avalon Peninsula<sup>1</sup> and 0.00667/year for the other sections<sup>2</sup>.
